

DAY-4

1.Open your desktop or laptop, locate the RAM slots, and remove and re-insert the RAM module to simulate reseating — then document each step you took and any issues you observed during the process.

- First turned off the computer and unplugged the power cable.
- Then opened the computer case carefully.
- Then located the RAM slots on the motherboard.
- Then pressed the clips on both sides of the RAM slot to remove the RAM module.
- Then checked the RAM and slot for any dust or damage.
- Then aligned the notch on the RAM with the slot and inserted it back firmly.
- Then pressed the RAM until both side clips locked into place.
- After that closed the computer case, connected the power cable, and turned on the computer.
- The computer started normally, and the RAM was detected correctly

**2.Create a troubleshooting checklist for diagnosing a faulty GPU in a gaming PC, including at least 5 steps from initial symptom identification to confirming the fix.

Hint: Think about display issues, driver checks, and physical connections.**

- Check if the monitor shows a display or if the screen is blank.
- Make sure the GPU is properly inserted into the PCIe slot and the power cables are connected.
- Restart the computer and check if the GPU is detected in Device Manager.
- Update or reinstall the graphics driver from the GPU manufacturer's website.
- Test the GPU with another monitor or another PCIe slot, if available.
- Restart the computer and check if the display works normally

3.Simulate a storage issue by unplugging and replugging a SATA or NVMe drive (SSD/HDD) on a test system, then describe the error messages or BIOS indicators you see before and after reconnecting.

1. Frist I turned off the computer and disconnected the power cable.

2. Then I unplugged the SATA/SSD from the motherboard.
3. Then I turned on the computer and opened the BIOS.
4. The BIOS showed "No Boot Device Found" because the storage drive was disconnected.
5. Then I turned off the computer and connected the SATA/NVMe drive properly.
6. After that I restarted the computer and checked the BIOS again.
7. The BIOS detected the storage drive, and Windows started normally.

4. Given a scenario where a PC randomly restarts, list which component (RAM, GPU, storage) you would check first and explain your reasoning, then outline the specific diagnostic steps you would perform for that component.

I would check the RAM first because loose or faulty RAM is a common cause of random restarts and system crashes.

- First turn off the computer and unplugged the power cable.
- Then opened the computer case and located the RAM.
- After removing the RAM and cleaned the contacts carefully.
- Then reinserted the RAM firmly into the slot.
- Then started the computer and checked if it restarted again.
